

Workforce & Client-Fulfillment Analytics

An analytical read-out of the Power BI staffing dashboard — Jan–Apr 2020

Prepared from: A_DASHBOARD.pdf (Power BI Desktop export) • Scope: 4 locations, 10 staff, 160 service records • Period: January–April 2020

31,823

Total Hours Logged

15,712

Billable Hours

49.4%

Effective Billable Rate

160

Client Records Served

Effective billable rate is recomputed as Billable Hours ÷ Total Hours (15,712 / 31,823). The dashboard's own "Sum of Billable Rate %" and "Sum of Client Fulfillment %" cards (350.71K and 586.48K) are additive artifacts of summing a percentage field across every row — see Section 4 for why that number isn't usable on its own.

1. Executive Summary

The source dashboard tracks staffing activity for a home-visit or field-service operation spread across four locations and ten staff members between January and April 2020. Three findings stand out. First, workload is almost perfectly balanced across locations (24.5–25.7% each) and reasonably even across staff (a ~13% spread between the busiest and least busy person) — this is a well load-balanced roster, not one carried by a few individuals. Second, only about 49% of hours worked are billable, meaning roughly half of logged time sits outside the revenue-generating category, which is the single largest lever available for margin improvement. Third, both total and billable hours fall sharply in the final month of the window; because the underlying table is truncated well before 160 rows are fully enumerable from the visual alone, the more defensible reading is a partial final month in the extract rather than a genuine operational collapse — worth confirming against the live data model before acting on it.

Read this first

Every figure in this report is reconstructed from the visual dashboard export (chart shapes, axis scales, and the twelve visible detail rows), not from the underlying Power BI dataset. Section 5 documents exactly which numbers are exact (from the visible total row) versus estimated (read off chart bar/line positions). Treat estimated figures as directional, not audit-grade.

2. Distribution of Work: Location & Staff

Total hours split almost evenly across the four locations, with Location A carrying a marginally larger share (25.7%) and Locations B and D the smallest (24.6% each). A gap this narrow (about 1.2 percentage points, top to bottom) indicates deliberate scheduling or roughly equal demand at each site, rather than one location acting as an overflow hub for the others.

Total Hours by Location

Figure 1 — Total hours by location, reproduced from the dashboard's donut chart and legend percentages.

Total Hours Logged by Staff Member

Figure 2 — Total hours by staff member, ranked. Bar lengths are read from the source horizontal bar chart; exact hour counts are not labeled in the original and are approximated here.

At the individual level, Khalilah Gratz logs the most hours and Alvina Brazee the fewest, but the full roster sits inside a narrow band — roughly 3,040 to 3,430 hours per person over the period. That is a healthy sign for workload equity: no one staff member appears to be significantly over- or under-utilized relative to peers, which reduces both burnout risk on the high end and idle-cost risk on the low end.

3. Monthly Trend: Total vs. Billable Hours

Hours hold a stable, slightly upward pattern from January through March 2020, then drop sharply in the final month shown. The billable share of hours stays close to ~52–54% across the first three months before compressing in month four. Two explanations are consistent with the shape of the data: (a) April is a partial month in this extract — the dashboard was likely pulled mid-month, so April's bar simply has fewer days of data behind it; or (b) April 2020 coincides with the early COVID-19 disruption to in-person field and home-visit services in many regions, which plausibly suppressed both scheduled visits and billable activity. Both are speculative without the underlying row-level dates for April — this is flagged as the top open question in Section 6.

Figure 3 — Monthly total and billable hours. Jan–Mar values are estimated from the line chart's y-axis gridlines; the April drop is directional, matching the sharp decline visible in the source chart.

4. A Modeling Caveat Worth Fixing: Summed Percentages

Two of the four headline KPI cards in the source dashboard — "Sum of Billable Rate %" (350.71K) and "Sum of Client Fulfillment %" (586.48K) — are almost certainly misconfigured. Percentage fields (billable rate, fulfillment rate) are ratios; summing a ratio across every row of a fact table produces a number with no intrinsic meaning; it grows with row count, not with performance. The same pattern shows up in the "Sum of Billable Rate % by Name" chart below (Figure 4): it ranks staff from ~38,000 down to ~31,000, a scale that only makes sense as an additive rollup of a per-record percentage, not as an actual rate anyone worked at.

Figure 4 — Reproduction of the dashboard's "Sum of Billable Rate %" chart. The y-axis scale (tens of thousands) is the tell that this is a sum, not an average, of a percentage field.

Recommended fix

Switch both measures from SUM to AVERAGE (or, better, a true ratio measure such as `DIVIDE([Billable Hours],[Total Hours])` and `DIVIDE([Clients Served],[Clients Assigned])` in DAX). This alone would turn two of the four confusing headline KPI cards into numbers a reader can act on at a glance, without touching the underlying data model.

5. Data & Methodology

This report was built entirely from a single-page PDF export of a Power BI dashboard — no live data connection or underlying dataset was available. The table below separates what is exact (taken directly from the visible total row and legend labels) from what is estimated (read from chart proportions where no numeric label was printed).

Figure	Source in dashboard	Confidence
Total Hours = 31,823	Detail table total row	Exact

Billable Hours = 15,712	Detail table total row	Exact
Clients Assigned = 23,915	Detail table total row	Exact
Client records = 160	Detail table total row	Exact
Location shares (24.5–25.7%)	Donut chart legend labels	Exact
Per-staff total hours	Horizontal bar chart, no data labels	Estimated from bar length
Monthly Jan–Mar hours	Line chart, gridlines at 5K/10K	Estimated from line position
Monthly Apr hours	Line chart, sharp drop visible	Estimated, directionally reliable only
Sum of Billable Rate % by staff	Vertical bar chart, gridlines to 40K	Estimated from bar height

6. Open Questions & Recommendations

Open questions to resolve against the live model:

- Is April 2020 a complete month in the underlying data, or a partial extract? This single fact changes whether the drop is a real operational event or a reporting artifact.
- What does "Clients Assigned" (23,915) actually represent relative to "Clients Served" (160)? The two-order-of-magnitude gap suggests these are measuring different things (e.g., a running client-roster count vs. a visit-completion flag) and the labels should be clarified.
- Are the four locations comparable in staff headcount and client base, or does the near-equal hour split mask very different per-location workloads?

Recommended next steps:

- Convert the two summed-percentage KPI cards to true ratio measures (Section 4) — highest impact, lowest effort.
- Add a billable-vs-non-billable breakdown by reason code (travel, admin, no-show) to explain the ~51% non-billable share.
- Confirm the April data window and, if partial, either exclude it from month-over-month comparisons or annotate it on the chart so viewers don't misread a data gap as a demand collapse.
- Extend the by-staff view with a rolling 3-month trend to distinguish a temporary dip from a genuine staffing change.
